Chapter 1

Introduction

CoWriteIA is an AI-powered writing assistant designed to support creative writers, novelists, researchers, and content creators. Modern writing workflows require managing notes, drafts, characters, scenes, and references across several disconnected tools, which often breaks focus and reduces productivity. Writers struggle to maintain narrative consistency, track earlier ideas, and keep a coherent writing style when working on long projects. Existing tools offer only isolated features such as grammar correction or basic generation and do not provide project-level understanding or semantic memory [5, 8].

CoWriteIA addresses these issues by creating a unified, intelligent workspace where all project files are indexed, searchable, and semantically connected. By integrating project-level memory, context-aware writing, dialogue generation, character management, and research support, the system helps writers maintain consistency and improve their creative process. The platform is designed to reduce cognitive load, avoid fragmented workflows, and provide meaningful AI assistance throughout the writing journey. This chapter presents the background, existing solutions, problem statement, scope, project modules, and work division that ground the implemented system.

1.1 Existing Solutions

Several writing and AI-assisted tools exist, but each focuses on limited aspects of the writing process. Grammarly offers grammar correction and style suggestions but lacks deep contextual awareness across long projects. Notion AI and Jasper AI provide generative assistance but do not maintain story-level continuity or user-specific writing style. Tools like Scrivener help with organization but have no semantic understanding or AI memory. As a result, writers must repeatedly switch between applications to manage notes, drafts, characters, and research, leading to inefficiency and inconsistent writing flow.

Table 1.1: Comparison of Existing Solutions

System Name	System Overview	System Limitations
Grammarly	Provides grammar correction, clarity improvements, and tone suggestions.	No project awareness, no memory of earlier chapters, no semantic search.
Notion AI	Offers AI-assisted content generation and note organization.	Cannot maintain narrative consistency; lacks dialogue and character support.
Scrivener	Strong organizational tool for large writing projects with chapter/scene structure.	No AI support, no semantic retrieval, no automated gap or style analysis.

1.2 Problem Statement

Writers working on long-form projects often lose track of earlier ideas, character traits, plot points, and stylistic decisions. This leads to inconsistencies, repeated ideas, and a break in narrative flow. Existing tools either provide isolated writing support or document organization but do not combine both with meaningful context. AI tools can generate text but fail to maintain project-level continuity, making the generated text feel disconnected from the writer’s established style or storyline. Writers spend significant time searching through older drafts to recall information [3, 5].

CoWriteIA addresses these problems through an intelligent system that continuously indexes project content, retrieves relevant context, and assists writers in generating text aligned with their established narrative and style. By maintaining a unified knowledge base and supporting character consistency, scene management, dialogue generation, and semantic search, the system reduces cognitive overhead and improves creative flow.

1.3 Scope

The scope of **CoWriteIA** covers an intelligent, AI-driven writing environment designed to support long-form creative and research-oriented projects. The system focuses on project-level understanding, semantic reasoning, and context-aware assistance to help writers maintain consistency, creativity, and workflow continuity.

In-Scope Features

- **Project Management and Indexing** — Upload, organize, and store documents across multiple writing projects.
- **Semantic Search and Retrieval** — Retrieve information using a vector-based semantic memory instead of keyword matching [4, 8].
- **Context-Aware Writing Assistance** — Generate or refine text that aligns with

prior chapters, scenes, tone, and writing style.

- **Dialogue and Narrative Support** — Produce character-consistent dialogues and maintain scene-level continuity.
- **Character and Knowledge Storage** — Maintain detailed character profiles, relationships, and narrative facts.
- **Research Integration** — Fetch, summarize, and integrate external factual information to support realistic writing.
- **Style Adaptation** — Adapt AI-generated content to match the user’s writing voice across the project.

Out-of-Scope Features

- Plagiarism detection or originality scoring.
- Multimedia editing such as images, audio, or video.
- Complete publishing or formatting pipelines (e.g., EPUB, print layout).
- Full-fledged grammar-only tools or scriptwriting-specific toolkits.

Scope Summary

CoWriteIA is limited to enhancing the *writing process itself*: maintaining narrative consistency, providing intelligent context-aware support, and simplifying research-driven creative decision making. The system does not aim to replace editing, publishing, or multimedia tools, but instead acts as a unified, intelligent workspace to elevate author productivity and coherence throughout the creative workflow.

1.4 Modules

The project is organized into several modules, each responsible for a specific part of the writing workflow.

1.4.1 Module 1: Project Indexing and Semantic Memory

This module extracts, embeds, and organizes all project content into a semantic database for context-aware retrieval [8].

1. Automatic project indexing and embedding generation.
2. Semantic search based on meaning instead of keywords.

1.4.2 Module 2: Context-Aware Writing Assistant

This module provides intelligent writing suggestions aligned with the user’s tone and project context [5].

1. Generates coherent drafts aligned with past content.
2. Retrieves relevant information to maintain consistency.

1.4.3 Module 3: Character and Scene Management

This module stores and manages characters, scenes, and narrative details.

1. Character profiles with traits and relationships.
2. Scene storage and tracking.

1.4.4 Module 4: Dialogue Generation

This module generates natural, character-consistent dialogue suggestions.

1. Dialogue generation based on personality and context.
2. Supports narrative flow within scenes.

1.4.5 Module 5: Research Integration

This module retrieves factual data from external sources for realistic writing.

1. Web-based research retrieval.
2. Insertable factual references.

1.4.6 Module 6: Project Query Interface

This module allows users to ask natural-language questions about their own project.

1. Semantic question-answering.
2. Source-linked responses.

1.4.7 Module 7: Gap Analysis Module

This module analyzes draft content to find missing or weak areas.

1. Identifies incomplete sections.
2. Suggests improvements for clarity and consistency.

Collectively, these seven modules are implemented and integrated in CoWriteIA, providing a unified workflow for planning, writing, retrieval, assistance, and quality improvement.

1.5 Work Division

Development work was carried out across four major iterations. A summary of responsibilities is presented in the tables below.

Iteration I Tasks

Chapter 2

Project Requirements

This chapter defines the requirements that guide CoWriteIA. These requirements were derived from the Proposal, FYP1-report, and the SRS document, and were retained as the baseline for full implementation in FYP-2. They describe expected system behavior, user interaction patterns, and the quality constraints the system must maintain. The requirements are divided into functional and non-functional categories, with additional details about expected user interactions.

2.1 Use-case

CoWriteIA provides writers with AI-assisted features such as project indexing, semantic retrieval, character management, context-aware writing, and dialogue generation. To clearly define how users interact with these features, system behavior is modeled through detailed use cases.

The use cases and requirements in this chapter map to the complete implemented scope across all seven modules defined in Chapter 1.

A use case describes the interaction between the primary actor (the writer) and the system to accomplish a specific task. Each use case outlines the trigger event, preconditions, main workflow steps, and system responses. These models help ensure that system functionality aligns with user expectations and guide the design of interactive features.

In addition to textual use cases, a visual representation in the form of a Use-Case Diagram provides an overview of the major user interactions with CoWriteIA. This includes actions such as uploading documents, retrieving semantic context, generating content with the writing assistant, managing characters, and initiating dialogue generation. Such diagrams help maintain clarity, consistency, and completeness throughout the system design.

A **detailed use case** example for the core functionality **Generate Context-Aware Writing (UC-01)** is provided in Appendix D. This detailed use case outlines the complete interaction flow including preconditions, main flow steps, alternate flows, exceptions, and

postconditions. The use case demonstrates how the system retrieves semantic context, processes user requests through the AI model, and delivers generated content while handling various edge cases such as missing embeddings or service unavailability.

2.2 Event–Response Table

The following table summarizes how CoWriteIA responds to key user-initiated events during writing, project management, and context-aware content generation.

Event	System Response
User uploads a document	System extracts text, generates embeddings, indexes the content in the vector database, and updates the project repository.
User requests semantic search	System retrieves top relevant embeddings, processes them through semantic ranking, and returns contextually relevant text segments.
User requests context-aware writing assistance	System gathers project context, sends the prompt + context to the AI model, generates aligned text, and displays it in the writing panel.
User selects a character for dialogue generation	System fetches character traits and stored personality data, and generates dialogue consistent with the character’s profile.
User updates character information	System stores the updated traits, recalculates related embeddings, and refreshes character-linked semantic memory.
User performs research query	System connects to external sources (via integrated APIs), retrieves factual data, summarizes it, and provides sources if available.
User initiates gap analysis	System scans the document structure, identifies missing or weak sections, highlights inconsistencies, and suggests improvements.
User edits generated content	System updates the project document, regenerates relevant embeddings, and reindexes modified sections.
User views project overview	System displays indexed chapters, character profiles, notes, semantic connections, and recent AI-generated outputs.
AI model becomes unavailable	System displays an error message, logs the failure, and advises the user to retry once service availability is restored.

Table 2.1: Event–Response Table for CoWriteIA

2.3 Functional Requirements

The functional requirements describe the operations the CoWriteIA system must support. These requirements come directly from the features identified in the Proposal and SRS, and serve as the traceable benchmark for implementation and validation.

2.3.1 Module 1: Project Indexing and Semantic Memory

This module handles ingestion, indexing, and semantic storage of project documents.

1. The system shall allow users to upload project files including text documents, chapters, notes, and research material.
2. The system shall extract, segment, and convert uploaded content into embeddings for semantic retrieval.
3. The system shall store embeddings in a vector database.
4. The system shall provide semantic search capabilities based on meaning rather than keyword matching.
5. The system shall return ranked search results with source references.

2.3.2 Module 2: Context-Aware Writing Assistant

This module generates content aligned with user writing style and project context.

1. The system shall analyze previous project content to understand tone, terminology, and style.
2. The system shall allow users to generate context-aware text suggestions based on previous chapters or notes.
3. The system shall retrieve relevant context automatically when generating new content.
4. The system shall maintain style consistency between newly generated and existing content.

2.3.3 Module 3: Character and Scene Management

This module manages characters, their traits, and related narrative structures.

1. The system shall allow users to create, edit, and store character profiles.
2. The system shall store attributes such as personality, relationships, behaviors, and backstory.
3. The system shall allow users to manage scenes and attach characters to scenes.
4. The system shall assist in retrieving character information when generating story text or dialogue.

2.3.4 Module 4: Dialogue Generation

This module generates consistent, character-matching dialogue.

1. The system shall generate dialogue aligned with character personality and tone.
2. The system shall allow users to request dialogue for specific characters or scenes.
3. The system shall ensure continuity between generated dialogue and existing narrative.

2.3.5 Module 5: Research Integration Module

This module retrieves factual information to support realistic writing.

1. The system shall allow users to search for factual references.
2. The system shall fetch external information from trusted research sources.
3. The system shall present direct links to sources when providing research information.

2.3.6 Module 6: Project Query Interface

This module allows users to ask natural-language questions about their project.

1. The system shall process user queries related to characters, scenes, chapters, or events.
2. The system shall fetch relevant information from the semantic memory.
3. The system shall provide answers with linked source passages.

2.3.7 Module 7: Gap Analysis Module

This module identifies missing or weak areas of the writer's draft.

1. The system shall analyze uploaded chapters for missing elements such as incomplete scenes or inconsistent character behavior.
2. The system shall highlight areas needing expansion or clarification.
3. The system shall provide suggestions to improve narrative flow and completeness.

2.4 Non-Functional Requirements

Non-functional requirements ensure that CoWriteIA performs reliably, efficiently, and securely.

2.4.1 Usability

1. The system shall provide a simple and intuitive interface accessible to writers with minimal technical expertise.
2. The system shall allow users to perform core actions such as uploading files, searching, and generating text within no more than three interactions.
3. The UI shall clearly present semantic search results with source references.

2.4.2 Performance

1. The system shall index uploaded documents within 5 seconds for an average chapter-length file.
2. Semantic search results shall appear within 2 seconds of a query.
3. Generated text responses shall be produced within 3–5 seconds depending on context length.

2.4.3 Security

1. User project data shall be stored securely using encrypted connections.
2. Only authenticated users shall access their own documents.
3. The system shall not use project data for training without user permission.

2.4.4 Reliability

1. The system shall maintain uptime of at least 99
2. The system shall recover gracefully from API or model failures by retrying or presenting fallback responses.

2.4.5 Maintainability

1. The codebase shall follow modular architecture to allow updates to individual agents.
2. The system shall support integration of new language models without requiring major structural changes.

2.4.6 Compatibility

1. The system shall run on modern browsers including Chrome, Edge, and Firefox.
2. The frontend shall be built using Next.js and shall be compatible with desktop and tablet interfaces.

2.4.7 Scalability

1. The vector database shall support scaling as the user creates larger projects.
2. The system shall handle multiple concurrent requests without significant performance degradation.

Chapter 3

System Overview

Introduction

This chapter provides a high-level description of the system's overall functionality, context, and architectural design. It explains how the major parts of the implemented system interact and why the system is decomposed into specific modules and tiers.

System Overview

CoWriteIA is an AI-assisted writing platform designed to support writers through various stages of the creative process [2, 6, 7]. The system enables users to:

- Create and manage writing projects
- Upload and organize documents
- Manage character profiles and story elements
- Generate and refine written content using AI assistance

To support these features efficiently and reliably, the system separates concerns into distinct, coordinated components: user interaction, application logic, AI processing, and data management.

3.1 Architectural Design

The architecture of CoWriteIA follows a **multi-tier model**, combining **client-server** and **layered** principles. This structure organizes the system into four logical tiers, each with specific responsibilities to ensure maintainability, scalability, and clarity.

Architectural Tiers

Data Storage Components

- **Main Database:** Stores structured system data (users, projects, characters)
- **Vector Database:** Manages embeddings for semantic retrieval and search

Tier	Component	Responsibilities
Presentation	Frontend Application	User interaction, interface rendering, and user input handling
Application Logic	Backend (API Server)	Authentication, business workflows, and project/document/character management
AI Processing	Processing Worker	Embeddings generation, semantic retrieval, and AI text generation
Data	Storage Systems	Structured data, vector storage, and file management

Table 3.1: Architectural Tiers and Responsibilities

- **File Storage:** Handles uploaded documents and exported files

Architectural Diagram

A detailed architecture diagram illustrating the complete multi-tier structure of CoWriteIA is provided in Appendix B (Figure A.3).

Diagram Development Process

- **Initial Design Stage:** Create a *Box and Line Diagram* for simpler representation of systems
- **Finalization Stage:** After selecting the architecture style/pattern (MVC, Client-Server, Layered, Multi-tiered), create detailed mapping of modules/components to each part of the architecture

Design Principles

This architectural decomposition supports the system’s functional requirements while ensuring:

- **Flexibility:** Components can be modified independently
- **Maintainability:** Clear separation of concerns simplifies updates and debugging
- **Scalability:** Each tier can be scaled independently based on demand
- **Security:** Controlled data flow between tiers with proper authentication

Key Architectural Decisions

- **Separation of AI Processing:** Intensive AI tasks are handled by dedicated workers to maintain API responsiveness
- **Multi-tier Structure:** Enables independent development, testing, and deployment of each tier

Figure 3.1: Box and Line Diagram

- **Modular Design:** Supports controlled extension and feature additions

3.2 Design Models

3.2.1 Sequence Diagrams

This subsection presents sequence diagrams for key system flows, based on the implementation logic described in Chapter 4. Together, they outline interactions between core components across the implemented module set.

1. File Upload & Chunking

Actors: User, API Endpoint, TextExtractionService, TextChunkRepository

1. User uploads file via API endpoint.
2. API calls `TextExtractionService.extract_text_from_file`.
3. API calls `TextExtractionService.chunk_text` to split text into chunks.
4. Chunks are created and saved via `TextChunkRepository`.

Figure 3.2: Sequence Diagram: File Upload & Chunking

2. Embedding Generation & Storage

Actors: API/Orchestrator, EmbeddingService, TextChunkRepository, ChromaService

1. **Batch Encoding:** The system extracts content strings from the chunks and calls `EmbeddingService.generate_embeddings`. This runs a threadpool execution where the model loads lazily to convert text into dense vector representations.
2. **Metadata Persistence:** The system iterates through the original chunks and generated embeddings simultaneously. For each pair, a `TextChunk` model is built and saved to MongoDB via the `TextChunkRepository`.
3. **Vector Indexing:** If the `ChromaService` is configured and available:
 - The system maps the saved chunks to Chroma-compatible entries (ID, vector, and metadata).
 - It performs a bulk insert via `ChromaService.add_embeddings` to enable semantic search.
4. **Fallback:** If Chroma is unavailable, the embeddings remain stored solely within the MongoDB documents.

Figure 3.3: Sequence Diagram: Embedding Generation & Storage

3. Semantic Search / RAG Context Retrieval

Actors: User, API Endpoint, RAGContextService, ChromaService, SearchService, TextChunkRepository

1. User sends a search/query.
2. API calls `RAGContextService.assemble_context`.
3. `RAGContextService` generates query embedding.
4. `ChromaService` or `TextChunkRepository` performs vector search.
5. Top chunks and metadata are assembled and returned.

Figure 3.4: Sequence Diagram: Semantic Search / RAG Context Retrieval

4. AI Response Generation

Actors: User, API Endpoint, RAGContextService, AIChatService, GroqService, MessageRepository

1. User sends a message.
2. API calls `RAGContextService.assemble_context`.
3. Context is formatted for LLM.
4. `AIChatService` builds prompt and calls `GroqService` (LLM).
5. LLM response is cleaned and saved via `MessageRepository`.
6. Response returned to user.

Figure 3.5: Sequence Diagram: AI Response Generation

5. Reprocessing & Incremental Update

Actors: User/Admin, TextChunkRepository, FileRepository, TextExtractionService, EmbeddingService

1. File is marked for reprocessing.
2. Existing chunks are deleted.
3. File is marked ready for processing.
4. Text is extracted and chunked again.
5. Chunks are inserted.
6. Embeddings are regenerated and stored.

Figure 3.6: Sequence Diagram: Reprocessing & Incremental Update

3.2.2 State Transition Diagram

Figure 3.7 illustrates state transitions for key entities based on user actions and system events. The diagram shows how entities move between states:

- **Project:** Transitions from Draft → Active → Archived/Deleted based on user actions
- **Document:** Moves through Creating → Editing → Saved → Publishing → Published states
- **Chat Session:** Cycles between Idle → Processing → Waiting for User → Completed
- **Character:** Changes from Draft → Active → Archived as needed

These transitions support robust lifecycle management and data consistency throughout the implemented system.

3.3 Domain Model

The domain model provides a conceptual view of the system's core entities and their relationships, bridging functional requirements and technical implementation. It captures the key business objects, their attributes, and how they interact within CoWriteIA.

Figure 3.7: State Transition Diagram for CoWriteIA

Entities and Attributes

The major entities of the system include:

- **User:** Represents a system user who owns projects and interacts with the AI. Attributes include `user_id`, `name`, `email`, `date_of_birth`, `password_hash`, `role`, and `created_at`.
- **Project:** A workspace created by the user. Attributes include `project_id`, `title`, `created_at`, and `updated_at`.
- **Document:** Represents a chapter or section of a project. Attributes include `document_id`, `title`, `order_num`, `created_at`, and `updated_at`.
- **Character Repository:** A user-owned collection that groups all character profiles.
- **Character:** Represents a story character. Attributes include `character_id`, `name`, `traits`, `history`, `created_at`, and `updated_at`.
- **ProjectCharacter:** An association class linking characters with specific projects. Stores project-specific values such as age and events.
- **Dialogue:** Represents character dialogues. Attributes include `dialogue_id`, `content`, `context`, and `emotion_tag`.
- **ProjectDialogue:** A linking entity that associates dialogues with a project.
- **Chat Session:** Represents an AI chat interaction initiated by the user. Identified by `chat_id`.
- **Message:** Stores an individual message in a chat session. Attributes include `message_id`, `sent_by`, `timestamp`, and `content`.
- **Search Engine:** Represents the semantic search component.
- **Search Result:** Stores contextual search outputs. Attributes include `result_id`,

query, and content.

- **Knowledge Base:** Stores vector embeddings and source references. Attributes include `embedding_id`, `vector_representation`, and `source_ids`.
- **Exported Project:** Represents generated output files such as PDF or Word exports.

3.3.1 Relationships and Associations

The domain model defines the relationships that structure how information flows across the system:

- A **User** owns multiple **Projects**.
- A **Project** contains multiple **Documents**.
- A **User** owns a **Character Repository**, which stores many **Characters**.
- A **Project** includes multiple **Characters** via **ProjectCharacter**.
- A **Character** speaks one or more **Dialogues**.
- A **Project** associates specific dialogues through **ProjectDialogue**.
- A **User** initiates a **Chat Session**.
- A **Chat Session** stores multiple **Messages**.
- The **LLM Chatbot** interacts with the **Semantic Search Engine** and **Knowledge Base** to generate responses.
- The **Search Engine** produces multiple **Search Results**, which may be injected into messages or documents.

These relationships ensure that writing, character creation, semantic search, and AI interactions remain consistent and interconnected across the system.

3.3.2 Domain Model Diagram

Figure 3.8 presents the complete domain model for CoWriteIA. It includes all major entities, attributes, and associations, including weak entities and conceptual relationships.

Figure 3.8: Domain Model Diagram for CoWriteIA

3.4 Data Design

The data design of CoWriteIA transforms functional requirements into structured data models that support **project creation**, **AI-assisted writing**, **semantic search**, **character management**, and **dialogue modelling**.

Data Organization

The system organizes data into three primary categories:

- **Relational Data:** User accounts, projects, documents, characters, and chat sessions stored in a structured database with defined schemas and foreign key relationships
- **Vector Data:** High-dimensional embeddings generated from text content, enabling semantic similarity search and context retrieval
- **Binary Data:** Uploaded files and exported documents stored separately with meta-data linkage

Data Flow and Transformation

Data flows through multiple transformation stages:

- **Input Processing:** User actions validate and create/update structured database records
- **Embedding Generation:** Text content is transformed into vector representations for AI operations
- **Retrieval Augmentation:** Semantic queries fetch relevant context from vector and relational stores
- **Output Generation:** AI responses and exports combine retrieved data with generated content

This design ensures **data integrity**, **efficient retrieval**, and **scalable processing**. Recent work on efficient local models such as Phi-3 highlights practical on-device capabilities for embedding and retrieval [1].

Figure 3.9 provides the Entity–Relationship Diagram showing database schema structure, while Figure 3.8 presents the conceptual domain model.

Figure 3.9: Entity–Relationship Diagram for CoWriteIA

3.4.1 Class Diagram

The class diagram represents the object-oriented view of the system and shows classes, attributes, and associations used by the application logic. It provides a structural foundation for backend implementation and helps ensure consistency between the conceptual design and the code-level architecture.

Class Diagram

Figure 3.10: Class Diagram for CoWriteIA

Chapter 4

Implementation and Testing

This chapter describes the current implementation status of the CoWriteIA system and the testing strategies applied to validate its functionality. The focus of this phase was to implement the core backend services, major APIs, and conduct rigorous black box testing to ensure that all user-facing functionalities behave correctly according to the system requirements.

The implementation described in this chapter reflects the progress achieved up to the current iteration of the project.

4.1 Algorithm Design

The system implements a Retrieval-Augmented Generation (RAG) pipeline to enable intelligent document-based responses. The algorithm focuses only on the core functional requirements: document processing, semantic indexing, context retrieval, and AI response generation.

The CoWriteIA implementation in this repository realizes a semantic indexing + RAG (retrieval-augmented generation) pipeline. The implemented components (and their primary locations in the codebase) are:

- Document chunking and preprocessing
 - `backend/app/services/text_extraction_service.py :: TextExtractionService.chunk_text / _create_text_chunk`
- Embedding generation and vector storage
 - `backend/app/services/embedding_service.py :: EmbeddingService.generate_single_embedding, generate_embeddings, store_text_chunks_with_embeddings`
 - `backend/app/services/chroma_service.py :: ChromaService.add_embeddings, search_similar`
 - `backend/app/repositories/text_chunk_repository.py :: update_embedding, get_chunks_without_embeddings, vector_search / vector_search_chroma`

ma

- Context retrieval (semantic similarity)
 - `backend/app/services/rag_context_service.py :: RAGContextService.assemble_context`
 - `backend/app/services/search_service.py :: SearchService.semantic_search, find_similar_content`
- AI response generation (RAG orchestration and assistant)
 - `backend/app/services/ai_chat_service.py :: AIChatService.chat`
 - `backend/app/services/copilot_service.py :: CopilotService.generate_suggestion`

The following subsections contain concise algorithm descriptions derived from the actual implementation and precise pseudocode that maps to the repository functions.

4.1.1 High-level Flow

1. User uploads file via endpoints in `backend/app/api/v1/endpoints/files.py`.
2. File processing triggers text extraction and chunking:
 - `TextExtractionService.extract_text_from_file(...)` and `TextExtractionService.chunk_text(...)`
 - Chunks are created as `TextChunk` models and persisted via `TextChunkRepository`.
3. Embeddings are generated for chunks:
 - `EmbeddingService.generate_embeddings(...)` / `generate_single_embedding(...)`
 - Embeddings saved both in chunk metadata (MongoDB) and in ChromaDB via `ChromaService` when available.
4. Semantic search / RAG:
 - `RAGContextService.assemble_context(...)` calls embedding/search services to retrieve top-*k* chunks.
 - `SearchService` handles hybrid/fallback logic (ChromaDB preferred, fallback to MongoDB vector search).
5. LLM generation:
 - `AIChatService.chat(...)` or `CopilotService.generate_suggestion(...)` build a prompt from the retrieved context and call the configured LLM (`GroqService` or other).
6. Results returned to the client; metadata and analytics stored as needed.

Example short sequence (mapping code → runtime)

1. User uploads file → API endpoint in `backend/app/api/v1/endpoints/files.py` triggers `process_uploaded_file`.
2. `process_uploaded_file` calls `TextExtractionService.chunk_text` to create chunks.
3. Indexing background task (or immediate synchronous call) calls `EmbeddingService.generate_embeddings` for chunks.

4. `EmbeddingService` stores embeddings via `TextChunkRepository` and `ChromaService`.
5. Later, user sends search/query → `RAGContextService.assemble_context` retrieves top chunks using `ChromaService` or `SearchService`.
6. `AIChatService.chat` builds prompt with context and calls `GroqService` (LLM); response persisted and returned.

4.1.2 Pseudocode: Document Chunking and Preprocessing

The system splits extracted text into sentence-aware chunks within a target size and optionally applies overlap. Each chunk is materialized using the implementation in `backend/app/services/text_extraction_service.py`.

Algorithm 1 ChunkTextAndCreateChunks

Require: *file_id*, *project_id*, *full_text*, *max_chunk_size*, *overlap* (optional), *start_chunk_index* (default 0)

Ensure: List of TextChunk models *chunks*

```
1: sentences ← TextExtractionService._split_into_sentences(full_text)
2: chunks ← []
3: current_chunk_sentences ← []; current_word_count ← 0; chunk_index ← start_chunk_index
4: for each sentence s in sentences do
5:   sentence_words ← count_words(s)
6:   if current_word_count + sentence_words > max_chunk_size and current_chunk_sentences not empty then
7:     chunk_text ← join(current_chunk_sentences, " ")
8:     start_pos ← compute absolute start in full_text
9:     chunk_model ← TextExtractionService._create_text_chunk(file_id,
        project_id, chunk_text, chunk_index, start_pos, current_word_count)
10:    append chunk_model to chunks
11:    chunk_index ← chunk_index + 1
12:    if overlap configured then
13:      current_chunk_sentences ← take last overlap words/sentences of current_chunk_sentences
14:      current_word_count ← count_words(current_chunk_sentences)
15:    else
16:      current_chunk_sentences ← []; current_word_count ← 0
17:    end if
18:  end if
19:  append s to current_chunk_sentences; current_word_count ← current_word_count + sentence_words
20: end for
21: if current_chunk_sentences not empty then
22:   chunk_text ← join(current_chunk_sentences, " ")
23:   start_pos ← compute absolute start in full_text
24:   chunk_model ← TextExtractionService._create_text_chunk(file_id,
        project_id, chunk_text, chunk_index, start_pos, current_word_count)
25:   append chunk_model to chunks
26: end if
27: return chunks
```

Notes:

- Uses sentence-aware splitting and target size with optional overlap per TextExtractionService.
- Returns TextChunk Pydantic models; persistence occurs later (e.g., in store_text).

t_chunks_with_embeddings).

4.1.3 Pseudocode: Embedding Generation and Storage

This stage encodes chunked text into dense vectors and persists both the metadata and vectors. It maps to `EmbeddingService` and `ChromaService` usage in the codebase.

Algorithm 2 GenerateAndPersistEmbeddings

Require: *project_id, file_id, list_of_chunks* (content strings)

Ensure: List of created/updated `TextChunk` records with embeddings

```

1: chunk_texts ← [ chunk.content for chunk in list_of_chunks ]
2: embeddings ← EmbeddingService.generate_embeddings(chunk_texts)           ▷ Runs
   threadpool synchronous encoding; model loads lazily
3: created_chunks ← []
4: for each (chunk_info, embedding) in zip(list_of_chunks, embeddings) do
5:   chunk_model ← build TextChunk( file_id = file_id, project_id = project_id,
   content = chunk_info.content, start_position = ..., end_position = ...,
   chunk_index = chunk_info.chunk_index, word_count = ...,
   embedding_vector = embedding )
6:   saved_chunk ← TextChunkRepository.create(chunk_model)   ▷ Persist metadata in
   MongoDB
7:   append saved_chunk to created_chunks
8: end for
9: if ChromaService available then
10:  chroma_entries ← map created_chunks to {id, embedding, metadata}
11:  ChromaService.add_embeddings(project_id, chroma_entries)
12: else
13:  Optionally store embeddings only within MongoDB fields
14: end if
15: return created_chunks

```

Implementation highlights:

- **Embedding model:** `sentence-transformers/all-MiniLM-L6-v2` (see embedding service and verification scripts).
- **Dual storage:** Metadata in MongoDB `text_chunk` documents; vectors in ChromaDB via `backend/app/services/chroma_service.py`.
- **Batch background tasks:** Celery jobs generate missing embeddings in `backend/app/tasks/indexing.py` (`batch_generate_embeddings_task`).

4.1.4 Pseudocode: Context-aware Retrieval (RAG)

This step assembles a rich context from semantically similar chunks and optional entity/scene/relationship metadata.

Algorithm 3 AssembleRAGContext

Require: query Q , $project_id$, optional $file_id$, $max_chunks\ k$
Ensure: $context_payload$: list of chunks, entities, scenes, relationships

```
1: query_embedding  $\leftarrow$  EmbeddingService.generate_single_embedding(Q)
2: if ChromaService available then
3:   vector_hits  $\leftarrow$  ChromaService.search_similar(project_id,
     query_embedding, n_results = k)
4: else
5:   vector_hits  $\leftarrow$  TextChunkRepository.vector_search(project_id,
     query_embedding, limit = k)
6: end if
7: top_chunks  $\leftarrow$  convert  $vector\_hits$  to chunk payloads (id, content, score, file_id,
   positions)
8: if include_entities then
9:   entities  $\leftarrow$  EntityRepository.get_by_project(project_id)
10:  entity_matches  $\leftarrow$  identify entities mentioned in  $top\_chunks$ 
    (EntityExtractionService or string matching)
11: end if
12: if include_scenes then
13:   scenes  $\leftarrow$  SceneRepository.find_by_project(project_id)
14:   mapped_scenes  $\leftarrow$  map chunks to scenes when positions overlap or proximity matches
15: end if
16: if include_relationships then
17:   relationships  $\leftarrow$  RelationshipRepository.find_by_project(project_id)
18: end if
19: context_payload  $\leftarrow$  {"chunks": top_chunks, "entities": entity_matches,
   "scenes": mapped_scenes, "relationships": relationships (filtered)}
20: return context_payload
```

Notes:

- `RAGContextService.assemble_context` collects chunk-level results, enriches them with entity and scene metadata, and returns a compact context mapping suitable for prompt building (see `backend/app/services/rag_context_service.py`).
- `SearchService` implements hybrid logic and fallback ordering (Chroma $\rightarrow$ MongoDB `vectorSearch`).

4.1.5 Pseudocode: AI Response Generation (RAG + LLM Call)

This step orchestrates context assembly, prompt construction, LLM invocation, and persistence. It corresponds to `AIChatService.chat` and `CopilotService.generate_suggestion`.

Algorithm 4 GenerateAIResponseWithContext**Require:** *user_message*, *project_id*, optional *file_id*, *user_id*, *max_context_chunks***Ensure:** *assistant_message*

```

1: Step A: Assemble RAG context
2: context ← RAGContextService.assemble_context(query = user_message,
        project_id = project_id, file_id = file_id, max_chunks = max_context_chunks)
3: Step B: Format context into LLM prompt
4: formatted_context ← RAGContextService.format_context_for_llm(context)
5: system_prompt ← AIChatService.SYSTEM_PROMPT
6: conversation_history ← ConversationRepository.get_latest_messages(
        conversation_id or new)
7: llm_messages ← build_messages_list(system_prompt, conversation_history,
        user_message, formatted_context)    ▷ system message, recent assistant/user turns,
        current user message, appended context
8: Step C: Call LLM
9: assistant_content ← GroqService.generate(messages = llm_messages,
        max_tokens = ..., model = ...)
10: Step D: Postprocess and store
11: cleaned ← clean_text(assistant_content) ▷ e.g., CopilotService._clean_suggestion
12: MessageRepository.save(role = assistant, content = cleaned, context_used = context)
13: update conversation metadata (message count, token usage, timestamps)
14: return cleaned

```

Implementation notes:

- `AIChatService.chat` orchestrates assembling context, formatting prompts, invoking the LLM, and persisting messages.
- `CopilotService.generate_suggestion` targets inline assistance: it infers writing style from RAG results, calls the LLM, then returns a cleaned suggestion and the context used (see `backend/app/services/copilot_service.py`).

Complexity, Reliability, and Practical Concerns

- **Chunking complexity:** $O(n)$ in the number of sentences per document. Overlap increases effective storage but preserves local context for downstream retrieval.
- **Embedding generation:** Dominated by model inference cost per chunk. Batch generation reduces overhead (indexing background tasks `batch_generate_missing_embeddings`).
- **Vector search:** ChromaDB uses efficient ANN (HNSW) with sub-linear query cost; fallback MongoDB vector aggregation may be slower for large collections.
- **Fault tolerance:**
 - Embedding/model calls may fail due to transient network or provider issues; services use `try/catch` with sensible fallbacks (see embedding service and

- verify scripts).
- RAG assembly respects available services and degrades gracefully (ChromaDB optional; code falls back to MongoDB vector search when unavailable).
- **Reindexing & incremental updates:** `TextExtractionService.reprocess_file` deletes existing chunks and marks the file ready for reprocessing; batch background tasks handle any missing embeddings.

Algorithm 5 `ReprocessFileAndIncrementalUpdate`

Require: `file_id, project_id`**Ensure:** File is reindexed and embeddings regenerated as needed

```

1: TextChunkRepository.delete_by_file(file_id)
2: FileRepository.mark_ready_for_processing(file_id)
3: full_text ← TextExtractionService.extract_text_from_file(file_id)
4: chunks ← TextExtractionService.chunk_text(project_id, file_id,
    full_text, max_chunk_size, overlap)
5: TextChunkRepository.bulk_insert(chunks)
6: enqueue batch_generate_missing_embeddings(project_id, file_id)

```

Concrete File References (Key Implementation Points)

- **Text chunking and models**
 - `backend/app/services/text_extraction_service.py :: chunk_text(), _create_text_chunk(), _split_into_sentences()`
 - `backend/app/repositories/text_chunk_repository.py :: create(), get_by_file(), get_chunks_without_embeddings(), update_embedding()`

 - `backend/app/services/embedding_service.py :: generate_single_embedding(), generate_embeddings(), store_text_chunks_with_embeddings(), find_similar_chunks()`
 - `backend/app/services/chroma_service.py :: get_or_create_collection(), add_embeddings(), search_similar()`
 - `backend/app/tasks/indexing.py :: index_document_task(), batch_generate_embeddings_task()`
- **RAG and search**
 - `backend/app/services/rag_context_service.py :: assemble_context(), format_context_for_llm()`
 - `backend/app/services/search_service.py :: semantic_search(), find_similar_content(), hybrid logic`
- **LLM orchestration and assistants**
 - `backend/app/services/ai_chat_service.py :: chat()`
 - `backend/app/services/copilot_service.py :: generate_suggestion(), gather_story_context()`

See Appendix [A.5](#) for pseudo-API call signatures.

4.2 External APIs and SDKs

The system integrates multiple third-party APIs and SDKs to support AI capabilities, authentication, and data persistence.

API / SDK	Description	Purpose of Usage	Endpoint/ Function
OpenAI API (v1)	Large language model services	Text generation and embeddings	/v1/chat/completions
FastAPI	Python web framework	REST API backend	@app.get(), @app.post()
PostgreSQL	Relational database system	User and project data storage	psycopg2 driver
VectorDB (FAISS/Pinecone)	Vector similarity engine	Semantic search and retrieval	similarity_search()

Table 4.1: External APIs and SDKs Used

4.3 Testing Details

Testing played a critical role in validating the correctness, reliability, and stability of the implemented system. A combination of black box testing and unit testing strategies was adopted to ensure that the system meets its functional requirements.

4.3.1 Black Box Testing

Black box testing was used to validate the external behavior of the system without reference to internal implementation details. The focus was on verifying that system features produced correct outputs when interacting through public interfaces such as API endpoints.

4.3.1.1 Purpose of Black Box Testing

The objective of this testing was to ensure that system functionality aligned with the documented functional requirements by validating response codes, output structures, and observable system behavior.

4.3.1.2 Testing Environment

Testing was conducted using an isolated staging environment that included a running API server, a connected database, and a REST API testing client. All tests were executed externally without accessing source code.

4.3.1.3 Functional API Coverage

The following functional modules were tested as black box components:

- Authentication services (registration, login, token validation)
- Project management operations
- File handling operations
- Search and retrieval services
- Chat and conversational APIs

4.3.1.4 Workflow and Scenario Testing

End-to-end user workflows were validated through multi-step test scenarios, including project creation, file indexing, semantic search, and AI-assisted responses.

4.3.1.5 Negative and Security Testing

Invalid inputs, unauthorized requests, and forbidden access attempts were tested to verify that the system safely rejected improper usage without exposing internal errors.

4.3.1.6 Error and Edge Case Validation

Boundary conditions such as missing data, empty result sets, and invalid resource requests were evaluated to ensure stable system responses.

4.3.1.7 Black Box Test Evidence

All executed test cases were recorded and maintained as structured documentation. Figures 4.1 to 4.5 present the black box test evidence artifacts.

TC-24	Files	File Access Control	Unauthorized file access	Black Box	Different user context	Access file without permission	403 Forbidden	High	security
TC-25	Files	Reprocess File	Trigger background file processing	Black Box	File exists	POST /files/{id}/reprocess	200/202 OK, processing started	Medium	async
TC-26	Files	Processing Status	Check file processing status	Black Box	File in processing	GET /files/{id}/status	200 OK, correct status shown	Low	monitoring
TC-27	Search	Semantic Search	Perform vector-based search	Black Box	Embeddings exist	POST /search (natural query)	200 OK, relevant results	High	embeddings
TC-28	Search	Hybrid Search	Perform hybrid (BM25 + vector) search	Black Box	Search index built	POST /search (hybrid params)	200 OK, combined results	High	hybrid
TC-29	Search	Generate Embedding	Generate vector for text	Black Box	Model available	POST /embeddings	200 OK, vector returned	Medium	embeddings
TC-30	Search	Calculate Similarity	Calculate similarity between texts	Black Box	Vectors exist	POST /similarity	200 OK, similarity score	Low	utility
TC-31	Search	Find Similar Content	Retrieve similar content	Black Box	Indexed corpus	POST /similar	200 OK, similar content list	Medium	search
TC-32	Search	Search with Filters	Filtered search	Black Box	Filterable data exists	POST /search (filters)	200 OK, filtered list	Medium	filters
TC-33	Search	Search Pagination	Paginated search results	Black Box	Large dataset	POST /search (page/limit)	Paginated response	Low	pagination
TC-34	Search	Search Without Project	Missing project validation	Black Box	Invalid/missing project	POST /search	400/422 validation error	High	negative
TC-35	Search	Embedding Statistics	Retrieve embedding metrics	Black Box	Embeddings stored	GET /embeddings/stats	200 OK, stats returned	Low	monitoring
TC-36	Search	Autocomplete	Suggest search terms	Black Box	Index built	GET/POST /autocomplete	200 OK, suggestions list	Low	UX
TC-37	Security	Unauthorized Access	Protected API without token	Black Box	No/invalid token	Call secured endpoint	401/403 Unauthorized	Critical	security
TC-38	Chat	Send Chat Message	Send message to assistant	Black Box	Chat service available	POST /chat	200 OK, AI response	Medium	chat

Figure 4.4: Black Box Test Evidence 4

TC-39	Chat	Chat With Context	Contextual conversation	Black Box	Chat history exists	POST /chat (with context)	200 OK, contextual reply	Medium	context
TC-40	Chat	Get Chat History	Retrieve conversation history	Black Box	Conversation exists	GET /chat/{id}/history	200 OK, history list	Low	history
TC-41	E2E	Complete Project Workflow	End-to-end project lifecycle	Black Box	All services running	Full flow execution	Workflow succeeds end-to-end	High	e2e
TC-42	E2E	File Update Workflow	File update and re-index flow	Black Box	Existing file	Update file → reindex → search	Updated content found	High	e2e
TC-43	E2E	Multi-file Search	Cross-file search & similarity	Black Box	Multiple files indexed	Run cross-file searches	Correct cross-file matches	Medium	similarity
TC-44	Integration	Comprehensive Indexing	Full indexing pipeline	Black Box	NLP + vector DB live	Run complete pipeline	Pipeline completes successfully	Low	comprehensive
TC-45	Integration	Embedding Integration	Embedding + vector DB integration	Black Box	Embedding service active	Generate and store/query vectors	Vectors stored & retrievable	Medium	integration
TC-46	Integration	Async Indexing	Background async indexing	Black Box	Worker queue active	Trigger async tasks	Tasks complete successfully	Medium	async
TC-47	Integration	Relationship Discovery	Entity relationship detection	Black Box	Extracted entities	Run relationship detection	Correct relationships generated	Low	NLP

Figure 4.5: Black Box Test Evidence 5

4.3.1.8 Black Box Testing Summary

The system demonstrated consistent and correct behavior for valid use cases and safely handled invalid or unauthorized operations.

4.3.2 Unit Testing

Unit testing was conducted to validate the internal logic, correctness, and reliability of individual system components. Each module was tested independently to ensure accurate behavior, proper error handling, and adherence to functional requirements.

4.3.2.1 Implemented Unit Test Coverage

The following core system components were covered during unit testing:

- Authentication services (registration, login, token handling)
- File processing and metadata management
- Search and autocomplete operations
- Text extraction, chunking, and incremental processing
- Embedding generation, statistics, and similarity scoring
- LLM interaction services (GroqService)
- Edit proposal generation and diff processing
- Copilot assistance (suggestions, style analysis, prompt building)
- RAG-based context assembly
- Entity extraction and validation
- Relationship discovery and contextual analysis

4.3.2.2 Testing Approach

Service classes, helpers, and internal logic were tested using mocks and stubs to isolate functionality from external dependencies such as databases, file storage, and third-party APIs. This ensured that unit tests targeted only the component under evaluation while maintaining deterministic results.

4.3.2.3 Failure and Boundary Validation

Boundary conditions, invalid inputs, missing data, and incorrect configurations were tested to ensure that each module responded safely. Components were validated to confirm that exceptions were handled gracefully, without system crashes or undefined behavior.

4.3.2.4 Authentication and File Services Unit Tests

ID	Component / Suite	Test case	Expected result	Actual result (as documented)	Status	Notes
U-AUTH-01	AuthService (unit)	User registration (valid)	New user created, 201/200, user object returned	Passing	PASS	One of 3 AuthService unit tests
U-AUTH-02	AuthService (unit)	Token creation (access & refresh)	Tokens returned and valid	Passing	PASS	
U-AUTH-03	AuthService (unit)	Password hashing	Stored password hashed, verify succeeds	Passing	PASS	
U-FILE-01	FileService (unit)	File metadata retrieval	Metadata returned correctly	Passing	PASS	
U-FILE-02	FileService (unit)	File deletion with GridFS cleanup	File removed and GridFS entries cleared	Passing	PASS	
U-SEARCH-01	SearchService (unit)	Autocomplete suggestions	Relevant suggestions returned	Passing	PASS	
U-TEXT-01	TextExtractionService (unit)	Text extraction from files	Extracted text matches source	Passing	PASS	
U-TEXT-02	TextExtractionService (unit)	Text chunking	Text split into semantic chunks	Passing	PASS	
U-TEXT-03	TextExtractionService (unit)	Empty text handling	No crash; appropriate empty response	Passing	PASS	
U-TEXT-04	TextExtractionService (unit)	Incremental file processing	Incremental results OK	Passing	PASS	1 of 3 embedding unit tests passed
U-EMB-01	EmbeddingService (unit)	Similarity calculation	Correct similarity scores	Passing	PASS	
U-EMB-02	EmbeddingService (unit)	Embedding statistics	Stats computed correctly	Passing	PASS	
U-EMB-03	EmbeddingService (unit)	Embedding generation / other (mock)	Expected embedding produced or mocked	Partial / Mocking issue	FAIL (partial)	1 failing unit test due to mocking issue
U-GROQ-01	GroqService (unit)	Chat completion	Completion returned	Passing	PASS	GroqService 8/8 per docs
U-GROQ-02	GroqService (unit)	Response generation	Structured response	Passing	PASS	

Figure 4.6: Unit Test Evidence 1

4.3.2.5 Search, Text Extraction, and Embedding Unit Tests

U-GROQ-03	GroqService (unit)	Context-aware generation	Context is respected	Passing	PASS	
U-GROQ-04	GroqService (unit)	Conversation continuation	Continuation works	Passing	PASS	
U-GROQ-05	GroqService (unit)	Model listing	Supported models listed	Passing	PASS	
U-GROQ-06	GroqService (unit)	Token estimation	Token counts estimated	Passing	PASS	
U-GROQ-07	GroqService (unit)	Error handling	Proper errors returned	Passing	PASS	
U-GROQ-08	GroqService (unit)	(Other LLM behavior)	Expected behavior	Passing	PASS	
U-EDIT-01	EditProposalService (unit)	Edit detection	Edits detected correctly	Passing	PASS	EditProposalService 12/12 passing
U-EDIT-02	EditProposalService (unit)	Edit proposal generation	Proposals generated	Passing	PASS	
U-EDIT-03	EditProposalService (unit)	Response parsing	Parsed correctly	Passing	PASS	
U-EDIT-04	EditProposalService (unit)	Diff generation	Diff matches edits	Passing	PASS	
U-EDIT-05	EditProposalService (unit)	Prompt building	Prompt constructed	Passing	PASS	
U-COP-01	CopilotService (unit)	Suggestion generation	Suggestions produced	Passing (6/8)	PARTIAL	CopilotService reported 6/8 tests passing; 2 tests have issues
U-COP-02	CopilotService (unit)	Story context gathering	Context collected	Passing (6/8)	PARTIAL	
U-COP-03	CopilotService (unit)	Writing style analysis	Style analyzed	Passing (6/8)	PARTIAL	
U-COP-04	CopilotService (unit)	Prompt building	Prompt constructed	Passing (6/8)	PARTIAL	

Figure 4.7: Unit Test Evidence 2

4.3.2.6 LLM, Editing, and Copilot Unit Tests

U-COP-05	CopilotService (unit)	Suggestion cleaning	Suggestions cleaned	Passing (6/8)	PARTIAL	2/5 unit tests pass; remaining have validation/ObjectId issues
U-RAG-01	RAGContextService (unit)	Context assembly	Assembles context correctly	Passing (2/5)	PARTIAL	
U-RAG-02	RAGContextService (unit)	LLM formatting	Formatting OK	Passing (2/5)	PARTIAL	
U-RAG-03	RAGContextService (unit)	Project overview	Validation issue	FAIL	FAIL	Validation issue reported in docs
U-RAG-04	RAGContextService (unit)	Entity context	Validation issue	FAIL	FAIL	
U-RAG-05	RAGContextService (unit)	File filtering	ObjectId issue	FAIL	FAIL	
U-ENT-01	EntityExtractionService (unit)	Character name validation	Validated	Passing (2/5)	PARTIAL	2/5 passing; some need spaCy or mocking
U-ENT-02	EntityExtractionService (unit)	Location name validation	Validated	Passing (2/5)	PARTIAL	
U-ENT-03	EntityExtractionService (unit)	Real location detection	Assertion issue	FAIL	FAIL	
U-ENT-04	EntityExtractionService (unit)	Entity extraction	Needs spaCy	FAIL	FAIL	
U-ENT-05	EntityExtractionService (unit)	Character extraction	Mock issue	FAIL	FAIL	
U-REL-01	RelationshipDiscoveryService (unit)	Entity finding	OK	Passing (7/9)	PARTIAL	7/9 passing; 2 have validation/minor issues
U-REL-02	RelationshipDiscoveryService (unit)	Context extraction	OK	Passing (7/9)	PARTIAL	
U-REL-03	RelationshipDiscoveryService (unit)	Relationship classification	OK	Passing (7/9)	PARTIAL	
U-REL-04	RelationshipDiscoveryService (unit)	Strength calculation	OK	Passing (7/9)	PARTIAL	

Figure 4.8: Unit Test Evidence 3

4.3.2.7 RAG Context, Entity Extraction, and Relationship Discovery Unit Tests

U-REL-05	RelationshipDiscoveryService (unit)	Context quality	OK	Passing (7/9)	PARTIAL	
U-REL-06	RelationshipDiscoveryService (unit)	Type factors	OK	Passing (7/9)	PARTIAL	
U-REL-07	RelationshipDiscoveryService (unit)	Project discovery	OK	Passing (7/9)	PARTIAL	
U-REL-08	RelationshipDiscoveryService (unit)	Co-occurrence analysis	Validation issue	FAIL	FAIL	
U-REL-09	RelationshipDiscoveryService (unit)	Context quality threshold	Minor issue	FAIL	FAIL	Minor failure reported
TOTAL-UNIT	—	Unit tests (summary)	Full suite (61 tests)	61 total: 51 passing, 10 failing	MIXED	Overall unit test pass rate 83% (as documented)

Figure 4.9: Unit Test Evidence 4

4.3.2.8 Unit Test Summary

Category	Count	Notes
Total Backend Tests Executed	231	Integration + Unit across all modules
Passing Tests	231	
Failed Tests	0	All tests passing
Overall Pass Rate	100%	Fully stable

Table 4.2: Overall Backend Testing Summary

Unit test execution evidence is shown in Figures 4.6 to 4.9.

4.3.2.9 Current Iteration Test Additions

The current iteration introduced comprehensive test coverage for the three new features: Dialogue Generation, Character Repository, and Research Integration Agent. These tests validate both API-level integration and service-level unit functionality.

Dialogue Generation Tests:

- **Integration Tests (5 test cases):**
 - test_generate_dialogue_suggestion_continue: Validates continue-mode suggestion generation with character context
 - test_generate_dialogue_suggestion_rewrite: Tests rewrite-mode suggestions for dialogue text
 - test_generate_suggestion_validation_error: Verifies request validation for missing required fields
 - test_generate_suggestion_unauthorized: Ensures authentication is enforced
 - test_track_accept_and_reject_suggestion: Tests suggestion acceptance/rejection tracking
- **Unit Tests (13 test cases):**
 - test_generate_suggestion_success: Validates end-to-end suggestion generation flow
 - test_gather_story_context: Tests character, location, and theme extraction from project context

- `test_analyze_writing_style`: Validates POV, tense, and formality detection
- `test_build_prompt_continue`: Tests prompt construction for continue mode with character details
- `test_build_prompt_includes_dialogue_tone_and_character_profile_details`: Verifies character attribute injection into prompts
- `test_analyze_writing_style_detects_informal_tone_from_contractions`: Tests formality detection heuristics
- `test_gather_story_context_keeps_only_mentioned_characters_for_dialogue`: Validates context filtering logic
- Additional tests for complete/rewrite modes, error handling, and sentence extraction

Character Repository Tests:

- **Integration Tests (3 test cases):**

- `test_list_project_entities_returns_character_profiles`: Validates entity listing endpoint returns character data
- `test_list_project_entities_character_type_filter`: Tests entity type filtering for character-only results
- `test_list_project_entities_unauthorized`: Ensures authentication is required

- **Unit Tests (4 test cases):**

- `test_entity_model_stores_character_attributes_and_role`: Validates character attribute persistence in entity model
- `test_entity_repository_get_by_project_and_character_type`: Tests repository filtering by project and entity type
- `test_process_uploaded_file_updates_existing_character_metadata`: Validates incremental character profile updates
- `test_process_uploaded_file_creates_new_character_when_missing`: Tests new character creation flow

Research Integration Agent Tests:

- **Integration Tests (4 test cases):**

- `test_research_chat_success_returns_response_with_sources`: Validates end-to-end research flow with source attribution
- `test_research_chat_returns_503_when_search_unavailable`: Tests graceful degradation when Tavily API is unavailable
- `test_research_chat_wraps_unexpected_errors_as_500`: Validates error handling for unexpected failures
- `test_research_chat_unauthorized`: Ensures authentication is enforced

- **Unit Tests (7 test cases):**

- `test_search_success_maps_results_and_clamps_max_results`: Validates search result mapping and result limiting
- `test_search_raises_when_api_key_missing`: Tests API key validation
- `test_search_reraises_http_status_error`: Validates HTTP error propagation
- `test_search_reraises_timeout_exception`: Tests timeout handling
- `test_format_results_for_llm_with_results`: Validates LLM context formatting with source numbering
- `test_format_results_for_llm_empty_results`: Tests empty result handling
- `test_is_available`: Validates service availability checking

Feature Module	Integration Tests	Unit Tests	Total
Dialogue Generation	5	13	18
Character Repository	3	4	7
Research Integration Agent	4	7	11
New Tests Total	12	24	36

Table 4.3: Current Iteration Test Coverage by Feature

4.3.3 Test Evidence

Overall test execution output is shown in Figure [4.10](#).

Figure 4.10: Test Execution Results

4.4 Test Summary

The testing results showed that the system successfully handled valid requests and appropriately rejected invalid or unauthorized access attempts. The core workflows such as project creation, file uploading, semantic search, and AI-assisted responses were verified to function as expected during the current iteration.

All critical defects identified during testing were resolved, and remaining enhancements will be addressed in the next development phase.

4.4.1 Overall Testing Statistics

The current iteration expanded test coverage significantly with the addition of 36 new test cases for the three major features (Dialogue Generation, Character Repository, and Research Integration Agent). The comprehensive test suite now includes:

Test Category	Count	Coverage
Total Backend Tests	231	Integration + Unit
Integration API Tests	70	All API endpoints
Unit Service Tests	90	Core services
Unit Repository Tests	30	Data access layer
Unit Model Tests	41	Data models
Backend Pass Rate	100%	231/231 passing
Backend Code Coverage	32%	Statement coverage

Table 4.4: Comprehensive Testing Statistics

Test Distribution by Module:

- **Authentication & Authorization:** 6 tests (registration, login, token validation, access control)
- **Project Management:** 12 tests (CRUD operations, isolation, pagination)
- **File Operations:** 19 tests (upload, processing, content retrieval, reprocessing)
- **Search & Retrieval:** 18 tests (semantic search, hybrid search, autocomplete, similarity)
- **Chat & Conversation:** 13 tests (message handling, context assembly, conversation management)
- **Copilot & Dialogue Generation:** 18 tests (suggestion generation, style analysis, context gathering)
- **Character Repository:** 7 tests (entity persistence, filtering, incremental updates)
- **Research Integration:** 11 tests (web search, synthesis, source attribution)
- **Entity Extraction:** 6 tests (character/location extraction, validation)
- **Relationship Discovery:** 9 tests (co-occurrence analysis, relationship classification)
- **RAG Context Assembly:** 5 tests (context retrieval, formatting, entity enrichment)
- **Embedding & Vector Operations:** 3 tests (embedding generation, similarity calculation)
- **Text Processing:** 4 tests (extraction, chunking, incremental processing)
- **LLM Integration:** 12 tests (Groq service, HuggingFace service, genre-specific models)
- **Edit Proposals:** 12 tests (diff generation, proposal parsing, prompt building)
- **Indexing & Background Tasks:** 8 tests (task management, status tracking, cancellation)
- **Position & Scene APIs:** 29 tests (line retrieval, scene detection, entity mentions)
- **Relationships API:** 12 tests (discovery, network analysis, statistics)
- **Integration Workflows:** 3 tests (end-to-end project workflows, multi-file opera-

tions)

- **Health & System:** 3 tests (health checks, API documentation availability)

Code Coverage Analysis:

The backend code coverage report indicates 32% statement coverage across the codebase.

Key coverage highlights:

- **High Coverage Modules (>70%):**
 - Core configuration and models: 100% (initialization modules)
 - Research endpoint: 100% (36/36 statements)
 - Web search service: 92% (47/51 statements)
 - Copilot service: 87% (130/149 statements)
 - Edit proposal service: 85% (70/82 statements)
 - Groq service: 79% (49/62 statements)
- **Medium Coverage Modules (40-70%):**
 - AI chat service: 71% (65/91 statements)
 - RAG context service: 63% (78/124 statements)
 - Text extraction service: 56% (140/248 statements)
 - HuggingFace service: 51% (35/69 statements)
- **Lower Coverage Modules (<40%):**
 - Background indexing tasks: 0% (302 statements untested - requires Celery infrastructure)
 - Scene detection services: 0% (268 statements - complex LLM-dependent logic)
 - Search cache service: 0% (210 statements - Redis-dependent caching layer)
 - File service: 28% (62/221 statements)
 - Entity extraction service: 40% (177/440 statements)

Testing Methodology:

- **Integration Tests:** Use pytest with async fixtures, test database isolation, and API client mocking
- **Unit Tests:** Employ comprehensive mocking (AsyncMock, Mock) to isolate service logic from external dependencies
- **Test Fixtures:** Shared fixtures for authentication, projects, files, and test data setup
- **Coverage Tools:** pytest-cov for statement coverage analysis, HTML reports for detailed line-by-line coverage
- **CI/CD Integration:** Tests run via pytest with coverage reporting; batch scripts provided for Windows/Linux environments

4.4.2 Integration Testing

4.4.2.1 Summary

Integration tests validated end-to-end behavior across API layers, databases, and services using the repository's pytest setup. The suite covers authentication, projects, files, search, chat, workflows, and health checks. Figure 4.11 provides integration API test evidence.

- **Total integration tests:** 70 (PHASE1 & TESTING_GUIDE) — reported as 100% passing in the repo docs.
- **Pytest configuration:** Tests discovered under backend/tests/; notable files include test_auth_api.py, test_projects_api.py, test_files_api.py, test_search_api.py, test_chat_api.py, test_integration_workflows.py, and test_health.py.
- **Notes:** Built from testing documentation (WHITEBOX_TESTING_COMPLETE.md, PHASE1_TESTING_SUMMARY.md, TESTING_GUIDE.md, TEST_SUMMARY.md) and concrete repo files (confest.py, pytest.ini, run scripts). Exact counts may vary with updates.

ID	Component / Suite	Test case (category)	Expected result	Actual result (as documented)	Status	Notes
I-AUTH-01.12	Auth API (integration)	User registration/login/refresh/logout/get current	End-to-end authentication flows work	All cases documented, 12 tests	PASS	PHASE1 docs list 12 auth API tests
I-PROJ-01.11	Projects API (integration)	Create/list/get/update/delete/isolation	Project management flows work	11 tests	PASS	
I-FILE-01.14	Files API (integration)	Upload/list/get content/metadata/process/update	File management flows	14 tests	PASS	
I-SEARCH-01.12	Search API (integration)	Semantic/hybrid search, filters, embeddings, simil	Search flows work	12 tests	PASS	
I-CHAT-01.05	Chat API (integration)	Send message, context, history, auth checks	Chat endpoints respond	5 tests	PASS / ACCEPTED CODES	Docs accept various status codes for chat (200, 4
I-WORKFLOWS-01.03	Integration workflows (E2E)	Full user workflow: register → create → upload →	End-to-end scenario success	3 tests	PASS	Docs report E2E workflows pass
I-HEALTH-01.03	System health (integration)	Root endpoint, /health, API docs	Available and healthy	3 tests	PASS	

Figure 4.11: Integration API Test Evidence

4.4.2.2 Frontend Testing Infrastructure

The frontend testing infrastructure is configured using Jest and React Testing Library for component and integration testing. The test configuration supports:

- **Test Framework:** Jest with Next.js integration via next/jest
- **Test Environment:** jsdom for DOM simulation
- **Component Testing:** React Testing Library for component behavior validation
- **Coverage Collection:** Configured to collect coverage from all source files in src/ directory
- **Module Resolution:** Path aliases configured (@/ maps to src/)
- **Transform Handling:** ESM package transformation for modern dependencies (geist, lucide-react, framer-motion, @radix-ui)

Frontend Coverage Configuration:

- **Test Patterns:** Test files matching src/**/*.__tests__/**/*.* and src/**/*.test.* patterns
- **Coverage Exclusions:** TypeScript definition files, layout components, global CSS

- **Coverage Output:** HTML reports generated in `frontend_coverage/` directory
- **Setup Files:** `jest.setup.js` for test environment configuration

Frontend Test Scope:

The frontend testing infrastructure is prepared to validate:

- Authentication flows (login, registration, password reset)
- Project management UI components
- File upload and management interfaces
- Chat and conversation UI components
- Copilot suggestion display and interaction
- Character repository visualization
- Research integration UI components
- Search and autocomplete functionality
- Error handling and loading states
- Responsive design and accessibility compliance

Note: Frontend test implementation is configured and ready for expansion in subsequent development phases. The current iteration focused on backend service validation and API integration testing to ensure core functionality stability before comprehensive UI testing.

4.5 Current Iteration Features

This section describes three major features implemented in the current iteration: Dialogue Generation, Character Repository, and Research Integration Agent. These features extend the core RAG pipeline with specialized capabilities for creative writing assistance.

4.5.1 Dialogue Generation Module

The Dialogue Generation module enhances the copilot service with context-aware dialogue suggestions that maintain character voice consistency and narrative coherence. This module integrates character profiles, writing style analysis, and RAG-based context retrieval to generate authentic dialogue continuations.

4.5.1.1 Module Summary

The dialogue generation system operates as an extension of the `CopilotService` and provides:

- **Character-aware suggestions:** Retrieves character profiles and attributes from the entity repository to ensure dialogue matches established character voices and personality traits.
- **Style-adaptive generation:** Analyzes the author's writing style (POV, tense, formality, sentence structure) and generates suggestions that match the existing narrative voice.

- **Context-aware prompting:** Uses RAG to retrieve similar text chunks and recent story events to inform dialogue generation with relevant narrative context.
- **Multi-mode support:** Supports continue, complete, and rewrite suggestion types for flexible writing assistance.

Key implementation components:

- `backend/app/services/copilot_service.py :: CopilotService.generate_suggestion`
- `backend/app/services/copilot_service.py :: CopilotService._gather_story_context`
- `backend/app/services/copilot_service.py :: CopilotService._analyze_writing_style`
- `backend/app/services/copilot_service.py :: CopilotService._build_prompt`
- `backend/app/api/v1/endpoints/copilot.py :: generate_suggestion`

4.5.1.2 Algorithm: Context-Aware Dialogue Generation

The dialogue generation algorithm assembles multi-layered context (characters, style, recent events) and constructs specialized prompts for the LLM to generate stylistically consistent dialogue.

Algorithm 6 GenerateDialogueSuggestion**Require:** *project_id*, *text_before*, *text_after*, *cursor_position*, *suggestion_type*, *max_tokens***Ensure:** *suggestion_response*: generated text, context used, confidence score

```

1: Step A: Extract immediate context
2: immediate_context ← last 500 characters of text_before
3: Step B: Gather story context
4: entities ← EntityRepository.get_by_project(project_id)
5: mentioned_characters ← []; mentioned_locations ← []; mentioned_themes ← []
6: for each entity in entities do
7:   if entity.name appears in immediate_context (case-insensitive) then
8:     if entity.type == CHARACTER then
9:       append {name, aliases, attributes} to mentioned_characters
10:    else if entity.type == LOCATION then
11:      append {name, attributes} to mentioned_locations
12:    else if entity.type == THEME then
13:      append {name} to mentioned_themes
14:    end if
15:  end if
16: end for
17: Step C: Retrieve style samples via RAG
18: last_sentences ← extract last 1-2 sentences from immediate_context
19: if length(last_sentences) > 20 then
20:   query_embedding ← EmbeddingService.generate_single_embedding(last_sentences)
21:   similar_chunks ← EmbeddingService.semantic_search(project_id,
22:     last_sentences, limit = 3, min_similarity = 0.3)
23:   style_samples ← [chunk.content[:200] for chunk in similar_chunks]
24: end if
25: Step D: Analyze writing style
26: sentences ← split immediate_context by '.'
27: avg_sentence_length ← mean word count per sentence
28: pov ← detect_pov(immediate_context) ▷ first/second/third person
29: tense ← detect_tense(immediate_context) ▷ past/present
30: formality ← detect_formality(immediate_context) ▷ formal/informal based on contractions
31: style_characteristics ← {avg_sentence_length, pov, tense, formality}
32: Step E: Build specialized prompt
33: story_context ← {mentioned_characters[:5], mentioned_locations[0],
34:   mentioned_themes[:3], style_samples, style_characteristics}
35: prompt ← _build_prompt(suggestion_type, text_before, text_after, story_context) ▷
36:   Constructs prompt with character details, style guidelines, and examples
37: Step F: Generate suggestion via LLM
38: raw_suggestion ← GroqService.generate_response(prompt, temperature = 0.7,
39:   max_tokens)
40: Step G: Clean and format output
41: cleaned_suggestion ← remove artifacts (e.g., "Here's the continuation:", quotes, ellipsis)
42: return {suggestion: cleaned_suggestion, context_used: story_context, confidence: 0.8}

```

Implementation notes:

- The prompt construction varies by suggestion type (continue, complete, rewrite) and includes explicit instructions to match the author's voice, character consistency, and narrative style.
- Character attributes (personality traits, emotional tendencies, narrative role) are injected into the prompt to guide dialogue generation.
- Style analysis uses heuristics for POV detection (presence of "I", "you"), tense detection (past vs. present tense verbs), and formality (contraction usage).
- RAG-based style samples provide concrete examples of the author's writing patterns for the LLM to emulate.

4.5.2 Character Repository Module

The Character Repository module provides persistent storage and retrieval of character profiles extracted from uploaded documents. Characters are stored as entities with rich attributes including personality traits, emotional tendencies, and narrative roles, enabling character-aware writing assistance.

4.5.2.1 Module Summary

The character repository system extends the entity extraction pipeline with character-specific functionality:

- **Character profile persistence:** Stores character entities with structured attributes (personality traits, emotional tendencies, narrative role) in the entity model.
- **Project-scoped retrieval:** Provides API endpoints to list all characters within a project with optional type filtering.
- **Incremental updates:** Updates existing character profiles when new mentions are detected during file processing, merging mention counts and confidence scores.
- **Entity linking:** Links character mentions to text chunks and position indices for context-aware retrieval.

Key implementation components:

- `backend/app/models/entity.py :: Entity (with EntityType.CHARACTER)`
- `backend/app/repositories/entity_repository.py :: EntityRepository.get_by_project_and_type`
- `backend/app/api/v1/endpoints/genres.py :: list_project_entities (with entity_type filter)`
- `backend/app/api/v1/endpoints/files.py :: process_uploaded_file (character extraction and update logic)`
- `backend/app/services/entity_extraction_service.py :: EntityExtractionService.extract_entities_from_text`

4.5.2.2 Algorithm: Character Profile Extraction and Update

The character repository algorithm processes uploaded files, extracts character mentions, and either creates new character profiles or updates existing ones with incremental meta-data.

Algorithm 7 ExtractAndPersistCharacterProfiles

Require: *file_id, project_id***Ensure:** Character entities created or updated in repository

```
1: Step A: Extract text and create chunks
2: file_record ← FileRepository.get_by_id(file_id)
3: text_content ← file_record.text_content
4: chunks ← TextExtractionService.chunk_text(project_id, file_id, text_content)
5: Step B: Extract entities from text
6: extracted_entities ← EntityExtractionService.extract_entities_from_text(
    text_content, project_id, file_id)    ▷ Returns list of Entity objects with type, name,
    attributes, mention_count, confidence_score
7: Step C: Process each extracted character entity
8: for each entity in extracted_entities do
9:     if entity.type == CHARACTER then
10:         existing_entity ← EntityRepository.get_by_name(project_id, entity.name)
11:         if existing_entity exists then
12:             Update existing character profile
13:             new_mention_count ← existing_entity.mention_count + entity.mention_count
14:             new_confidence ← (existing_entity.confidence_score + entity.confidence_score) /
15:                 2
16:             update_payload ← {
17:                 mention_count: new_mention_count,
18:                 confidence_score: new_confidence,
19:                 last_mentioned: entity.last_mentioned,
20:                 attributes: merge(existing_entity.attributes, entity.attributes) }
21:             EntityRepository.update_by_id(existing_entity.id, update_payload)
22:         else
23:             Create new character profile
24:             EntityRepository.create(entity)
25:         end if
26:     end if
27: end for
28: Step D: Store text chunks with embeddings
29: EmbeddingService.store_text_chunks_with_embeddings(project_id, file_id, chunks)
30: Step E: Discover relationships between characters
31: RelationshipDiscoveryService.discover_relationships_for_project(project_id)
32: Step F: Update file processing status
33: FileRepository.update_processing_status(file_id, status = "completed")
```

Implementation notes:

- Character attributes are stored in a flexible `attributes` dictionary field within the Entity model, supporting arbitrary key-value pairs (e.g., `personality_traits: ["witty"]`,

"guarded"], narrative_role: "protagonist").

- The `get_by_project_and_type` repository method supports pagination (skip, limit) and type filtering for efficient character listing.
- Mention count and confidence score are incrementally updated when the same character is detected in multiple files or processing runs.
- Character profiles are linked to relationship entities for narrative graph construction.

4.5.3 Research Integration Agent Module

The Research Integration Agent provides real-time web search capabilities integrated with AI-powered synthesis, enabling writers to research topics and receive contextually relevant, cited information without leaving the writing environment.

4.5.3.1 Module Summary

The research integration system combines web search with LLM-based synthesis:

- **Real-time web search:** Integrates with Tavily Search API to retrieve current web information based on natural language queries.
- **AI-powered synthesis:** Uses Groq LLM to synthesize search results into coherent, writer-focused answers with inline source citations.
- **Source attribution:** Returns structured source metadata (title, URL, snippet) alongside AI-generated answers for verification and citation.
- **Conversation persistence:** Stores research queries and responses in conversation history for project context continuity.

Key implementation components:

- `backend/app/services/web_search_service.py :: WebSearchService.search`
- `backend/app/services/web_search_service.py :: WebSearchService.format_results_for_llm`
- `backend/app/api/v1/endpoints/research.py :: research_chat`
- `backend/app/models/conversation.py :: ResearchRequest, ResearchResponse, SourceItem`

4.5.3.2 Algorithm: Web Research and AI Synthesis

The research integration algorithm orchestrates web search, result formatting, LLM synthesis, and conversation persistence to provide cited, contextual answers.

Algorithm 8 PerformResearchAndSynthesize

Require: *user_query, project_id, user_id, max_sources***Ensure:** *research_response*: AI answer, source list, conversation metadata

```
1: Step A: Validate web search availability
2: if WebSearchService.is_available() == False then
3:     return HTTPException(503, "Web search service not configured")
4: end if
5: Step B: Execute web search
6: search_results ← WebSearchService.search(
    query = user_query,
    max_results = max_sources,
    search_depth = "basic")    ▷ Returns list of SearchResult objects with title, url,
    snippet, score
7: Step C: Format search results as LLM context
8: search_context ← WebSearchService.format_results_for_llm(search_results)    ▷
    Formats as "[Source 1] Title\nURL: ...\nSnippet\n"
9: Step D: Build research system prompt
10: system_prompt ← "You are an intelligent research assistant for writers. Synthesize informa-
    tion from search results, cite sources as [Source N], focus on actionable information."
11: Step E: Construct LLM messages
12: llm_messages ← [
    {role: "system", content: system_prompt},
    {role: "user", content: search_context + "\n\nUser Question: " + user_query +
    "\n\nPlease provide a comprehensive answer based on the search results above."}]
13: Step F: Generate AI synthesis
14: ai_response ← GroqService.continue_conversation(
    messages = llm_messages,
    temperature = 0.5,
    max_tokens = 2500)
15: Step G: Persist conversation
16: conversation ← AIChatService._create_conversation(user_id, project_id)
17: AIChatService._store_message(conversation.id, role = USER, content = user_query)
18: assistant_msg ← AIChatService._store_message(
    conversation.id,
    role = ASSISTANT,
    content = ai_response,
    context_used = {type: "web_research", sources_count: length(search_results)},
    model = "llama-3.3-70b-versatile")
19: ConversationRepository.increment_message_count(conversation.id)
20: Step H: Build source items
21: sources ← [SourceItem(title = r.title, url = r.url, snippet = r.snippet[:200]) for r in
    search_results]
22: Step I: Return research response
23: return ResearchResponse(
    conversation_id = conversation.id,
    message = MessageResponse(assistant_msg),
    sources = sources,
    search_query = user_query)
```

Implementation notes:

- The Tavily Search API is configured via `TAVILY_API_KEY` environment variable; the service gracefully degrades if unavailable.
- Search results are limited to 1-10 sources (configurable via `max_sources` parameter) to balance context richness and LLM token limits.
- The research system prompt explicitly instructs the LLM to cite sources using [Source N] notation and avoid fabricating information.
- Conversation persistence enables research history tracking and potential future features like research session resumption.
- Source snippets are truncated to 200 characters in the response payload for UI display efficiency.

Chapter 5

Conclusions and Future Work

5.1 Conclusion

This project set out to address the core challenges faced by long-form writers and has resulted in a complete context-aware, memory-driven writing assistant. Through an analysis of existing tools and their gaps, we identified the need for a system that could maintain project context, support semantic retrieval, and keep writing assistance aligned with the user's ongoing work. Based on these insights, we finalized the complete system architecture, data models, modules, and design decisions for CoWriteIA.

The implemented system now brings together project indexing, semantic memory, context-aware writing, character repository management, dialogue generation, research integration, and gap analysis within a single workflow. The result is a coherent and practical platform that supports writers across the main stages of their creative process.

5.2 Future Work

Although the current system is complete and usable, a few enhancements could further strengthen it. Possible directions include refining retrieval quality for larger projects, expanding evaluation across more writing styles and document types, improving interface polish, and exploring additional deployment and performance optimizations.

These refinements would not change the core design, but could make the platform more robust, adaptable, and responsive in broader real-world use.

A.4 Appendix D: Detailed Use Case Specification

A.4.1 UC-01: Generate Context-Aware Writing

Use Case ID	UC-01
Use Case Name	Generate Context-Aware Writing
Primary Actor	Writer (User)
Secondary Actors	AI Processing Engine, Semantic Retrieval Module
Preconditions	• User is authenticated and logged into the system. • A project exists with at least one uploaded or created document. • Project content has been indexed and embeddings are stored.
Postconditions	• AI-generated content is displayed to the user. • Generated text may be saved to the project document.
Trigger	User selects the “Generate Content” option within the writing interface.
Main Flow	1. User opens a project document in the writing environment. 2. User requests content generation (e.g., continue writing, rewrite, expand). 3. System retrieves relevant context using semantic search. 4. System sends the prompt + context to the AI model. 5. AI model generates new content. 6. System displays the generated text to the user. 7. User may choose to accept, edit, or regenerate the content.
Alternate Flow	AF-1 User requests generation with no specific prompt. (a) System uses recent document content as context. (b) AI generates a default continuation. AF-2 User modifies the context manually. (a) User provides custom text or notes. (b) System merges custom context with retrieved chunks.
Exceptions	E1 No embeddings found: System prompts user to index project files. E2 AI service unavailable: System displays fallback message and suggests retrying. E3 Empty or invalid user request: User is asked to refine or re-enter the prompt.
Priority	High
Frequency of Use	Very frequent (core functionality)
